

## Chapter Name

# Making Sens of Data for Better Decisions

2024-03-18

## The Business *Pressures-Responses-Support* Model

Companies are moving aggressively to **computerized support** of their operations not only on operational but also on **decisional** level. Many **managerial actions** require computerized decision support (DSS).

Business **pressures** results from today's business climate, **responses** are actions taken by companies to counter the pressures (or to take advantages of the opportunities) and computerized **support** facilitates the monitoring of the environment and enhances the response actions taken by organizations

## Managerial Decision Making

- ☞ Managers usually make decisions by following a **four-step process**:
  1. **Define the problem** (i.e., a decision situation that may deal with some difficulty or with an opportunity).
  2. **Construct a model** that describes a real-world problem.
  3. **Identify possible solutions** to the modelled problem and **evaluate the solutions**.
  4. **Compare, choose and recommend** a potential solution to the problem.
- ☞ To follow this process one must **make sure** that:
  - **sufficient alternatives** are being considered
  - **The consequences** of using these alternatives can be **reasonably predicted**, and
  - **comparisons** are done **properly**.
- ☞ However a number of **environmental factors** make such an evaluation process **difficult**.

## The Need for Decision Support Systems

- ☞ Environments are growing more complex everyday, therefore making decisions today is indeed a **complex task**.
- ☞ It is **nearly impossible** to rely on a **trial-and-error** approach to management for the following reasons:
  - Technology, information systems, advanced search engines, and globalization result in **more and more alternative** from which to choose.
  - Government regulations and the need for compliance political instability and terrorism, competition, and changing consumer demands produce **more uncertainty**, making it more difficult to predict consequences and the future.
  - There is a **need to make rapid decisions**.
  - Making mistakes may be **very expensive**.
- ☞ Managers must be **more sophisticated**; they must use the **new techniques and tools** to support decision making.

## The Concept of Decision Support Systems

- ☞ In the **early 1970s**, Scott-Morton first articulated the **major concepts** of DSS.
  - He defined decision support systems (DSS) as „interactive computer-based systems, which help decision makers utilize **data** and **models** to solve unstructured problems” (Gory and Scott-Morton, 1971).
- ☞ The following is **another classic DSS definition**, provided by Keen and Scott-Morton (1978):
  - Decision support systems **couple** the intellectual resources of **individuals** with the capabilities of the **computer** to improve the quality of decisions. It is a computer-based support system for management decision makers who deal with semistructured problems.
- ☞ Note, that the term decision support system, like management information system (MIS) and other terms in the field of IT is a **content free expression** (i.e., it means different things to different people).
  - Therefore there is **no universally accepted definition** of DSS.
- ☞ Actually, DSS can be viewed as a **conceptual methodology** - that is a broad **umbrella term**.
  - However, some view DSS as a narrower, **specific** decision support **application**.

## DSS as an Umbrella Term

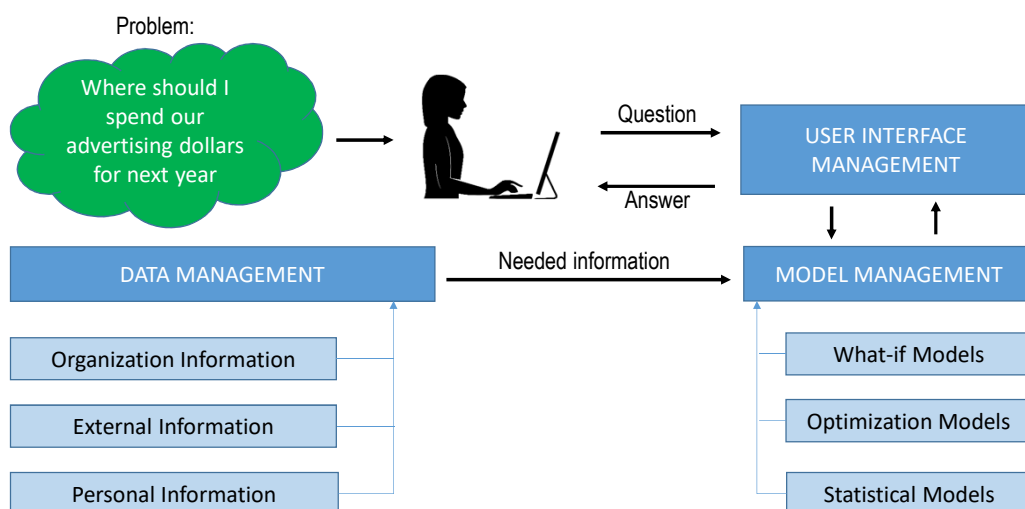

- ☞ The term DSS can be used as an **umbrella term** to describe **any** computerized system that supports decision making in an organization.
  - An organization may have a **knowledge management system** to guide all its personnel in their problem solving.
  - Another organization may have **separate** support systems for **marketing, finance, and accounting**; a supply chain management (SCM) system for **production**; and several rule-based systems for **product repair diagnostics** and **help desks**.
- ☞ DSS encompasses them **all**.

## From Data to Decisions

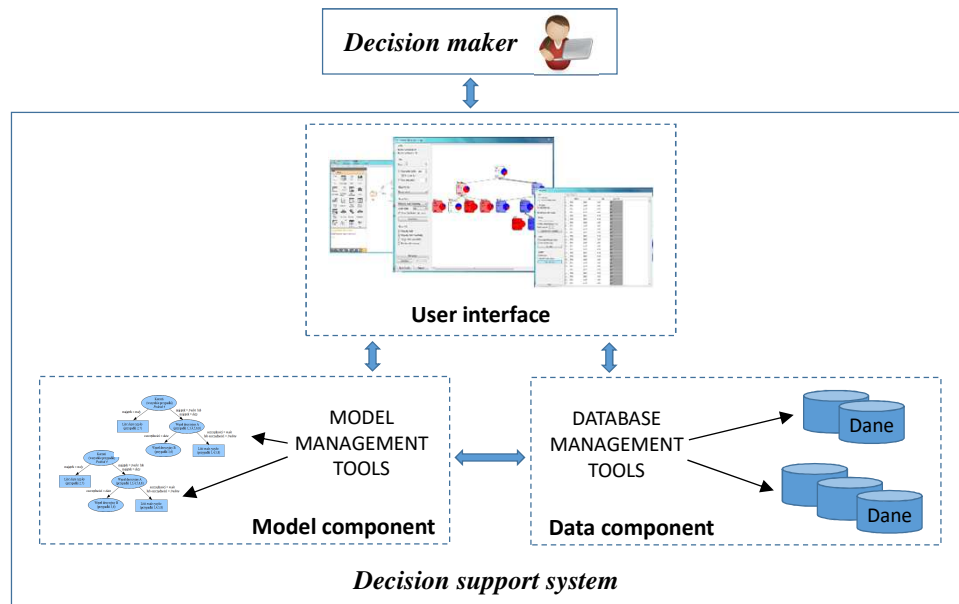

- ☞ The new techniques and tools to support decision making are focused on gaining profit from the **available data**.
- ☞ Making decisions requires **information** that is based on **data**. Data provides the information to support decisions, and so on.
  - Data in itself provides **no** judgment or interpretation and **no basis of action**.
  - The **context** and **use** of data turns it into information.
  - Connecting pieces of available information leads to **knowledge** that can then support decisions.

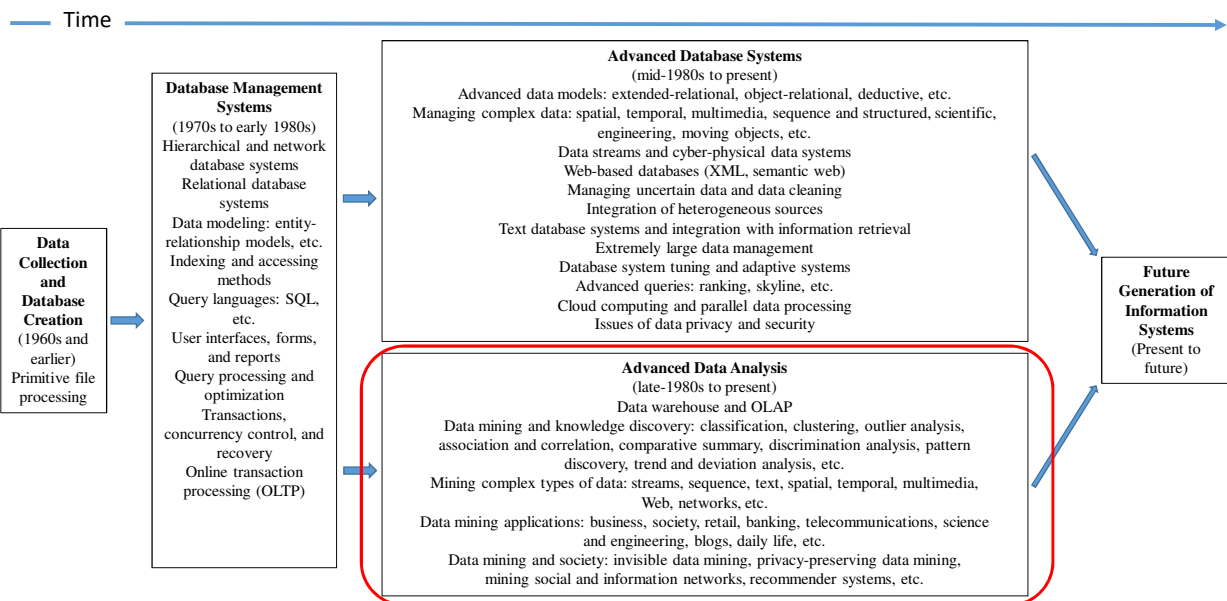

## Using a Decision Support System

## Components of a Decision Support System

## The evolution of database system technology

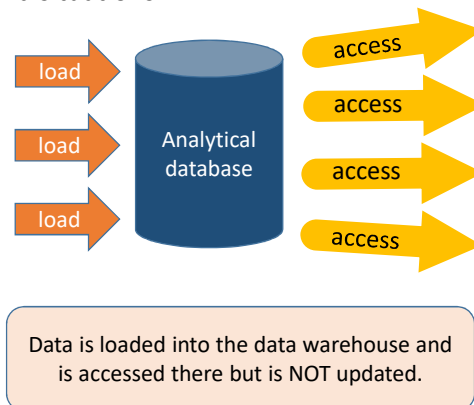

2024-03-18

## Operational vs. Analytical Databases

☞ **Operational** (e. g. relational) databases support everyday activity of a company.

☞ **Analytical or informational** databases (e. g. data warehouses) provide an information which can be used to analyze the problems and situations.

2024-03-18

## Data Driven Decision Support

- ☞ Historically, **Relational Database Management Systems** (RDBMSs) have been focused on the field of **Online Transaction Processing** (OLTP).
- ☞ **Data Warehousing** technology provided new possibilities to build data marts and data warehouses for **Decision Support Systems**.
- ☞ With **OLAP** and **data mining** features, we will be able to use the data accumulated in the OLTP databases to analyze, explain and even "predict" future data, e.g. consumer preferences, "what-if" analysis, etc.

2024-03-18

## Data Analysis Techniques

- ☞ A data warehouse is built to provide an **easy to access** source of **high quality** data.
  - It is a means to an end, **not** the end itself. That end is typically the need to perform **analysis and decision making** through the use of that source of data.
- ☞ There are several **techniques for data analysis** that are in common use.
  - **query** and **reporting** (formulate and display query results),
  - **multidimensional** analysis (analyze data content by viewing it from **different perspectives**), and
  - **data mining** (**discover patterns** and **clustering** attributes in the data that will provide further **insight** into the data content).

## Query and Reporting

- ☞ Query and reporting analysis is the **process** of
  - **posing a question** to be answered,
  - **retrieving relevant data** from the data warehouse,
  - **transforming** it into the appropriate context, and
  - **displaying** it in a readable format.

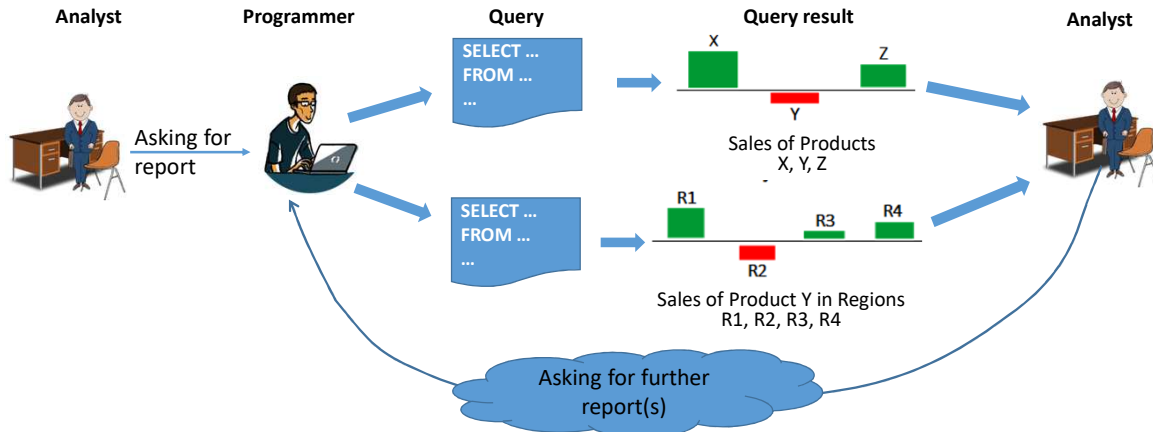

### The Process of Query and Reporting

- ☞ It is **driven by analysts** who must pose those questions to receive an answer.
  - You will find that this is **quite different**, for example, from data mining, which is **data driven**.

## Query and Reporting for Data Analysis

End users are primarily interested in processing **numeric values**, which they use to analyze the **behavior of business processes**, such as **sales revenue** and **shipment quantities**.

2024-03-18

## OLAP – Intuitively Explained

Using an OLAP tool the analyst can **browse** his data on multiple **levels** and **dimensions** in order to **explain** system's behavior.

2024-03-18

## Multidimensional Data Organization – Data Cubes

- ☞ Modeling data **multi-dimensionally** is a way to facilitate **on-line business analysis** and query performance.
- ☞ Using OLAP tool you can **browse your data** on multiple levels and dimensions in order to explain system's behavior

**Note:** Cubes are not limited to three dimensions.

2024-03-18

## Data Mining (1/2)

- ☞ Data mining is a **relatively new data analysis technique** which is very different from query and reporting and multidimensional analysis.
  - You do **not ask** a particular question of the data but rather **use specific algorithms** that analyze the data and report what they **have discovered**.
- ☞ **Unlike** query and reporting and multidimensional analysis where the user has to create and execute queries **based on hypotheses**, data mining **searches** for answers to questions that may have **not been previously asked**.
- ☞ The **discovery** could take the form of
  - finding **significance in relationships** between certain data elements,
  - clustering together of specific data elements, or
  - other patterns in the usage of specific sets of data elements.
- ☞ After finding these patterns, the algorithms can **infer rules**. These rules can then be **used** to generate a **model** that can **predict a desired behavior**, **identify relationships** among the data, **discover patterns**, and group **clusters of records** with similar attributes.

## Data Mining (2/2)

☞ In **industry**, in **media**, and in the **research** milieu, the term data mining is often used to refer to the **entire** knowledge discovery process (perhaps because the term is shorter than knowledge discovery from data).

- Therefore, we adopt a **broad view** of data mining functionality: Data mining is the **process** of discovering interesting **patterns** and **knowledge** from large amounts of data.
- As a knowledge discovery process, it typically involves data **cleaning**, data **integration**, data **selection**, data **transformation**, pattern **discovery**, pattern **evaluation**, and knowledge **presentation**.
- The **data sources** can include databases, data warehouses, the Web, other information repositories, or data that are streamed into the system dynamically.

☞ Data mining has **many successful applications**, such as business intelligence, Web search, bioinformatics, health informatics, finance, digital libraries, and digital governments.

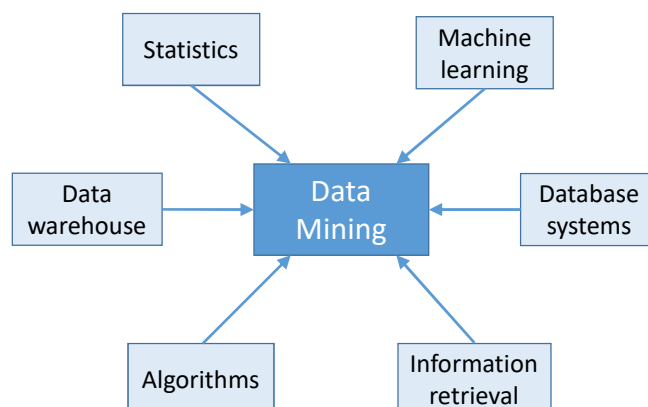

2024-03-18

## Which Technologies Are Used?

☞ Data mining, as a highly **application-driven** domain, has incorporated technologies from many **other domains**.

- These **include** statistics, machine learning, database and data warehouse systems, information retrieval, and **others**.

☞ The **interdisciplinary nature** of data mining research and development contributes significantly to the **success** of data mining and its extensive **applications**.

2024-03-18

## Roles in Data Mining

☞ **Database administrators** know where and how the company's data is stored, how to access it, and how to relate it to other data stores.

☞ **Domain experts** know the business environment, the processes, the customers, and the competitors.

☞ **Mining specialists** are the people with a background in data analysis who have at least basic statistical knowledge. They are able to apply data mining techniques and interpret the results in a technical way.

2024-03-18

## Data Mining Functionalities

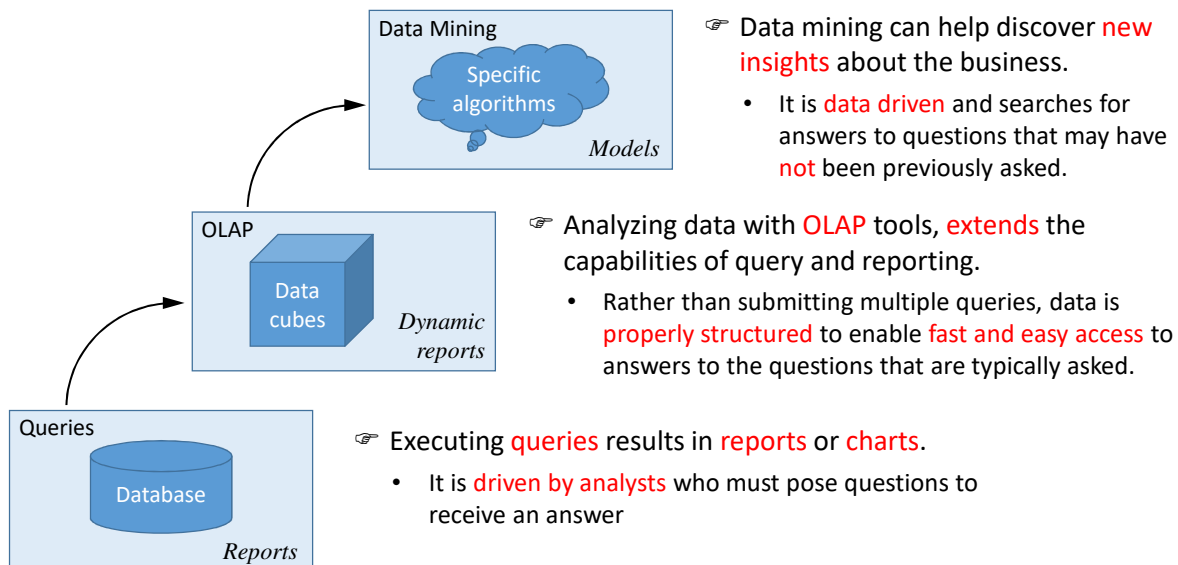

☞ Data mining functionalities are used to **specify the kinds of patterns or knowledge** to be found in data mining tasks. The functionalities include

- **characterization** and **discrimination**;
- the mining of **frequent patterns**, **associations**, and **correlations**;
- **classification** and **regression**;
- **cluster** analysis; and
- **outlier** detection.

☞ As new **types** of data, new **applications**, and new analysis **demands** continue to emerge, there is no doubt we will see more and more novel **data mining tasks** in the future.

## Evolution from Queries to Data Mining

2024-03-18

## Role of Analyst

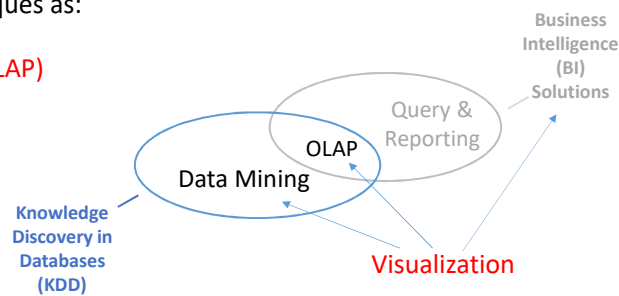

2024-03-18

## Knowledge Discovery in Databases

☞ The term *Knowledge Discovery in Databases* (KDD) refers to the broad process of **finding knowledge in data**, and emphasizes the "high-level" application of particular data mining methods.

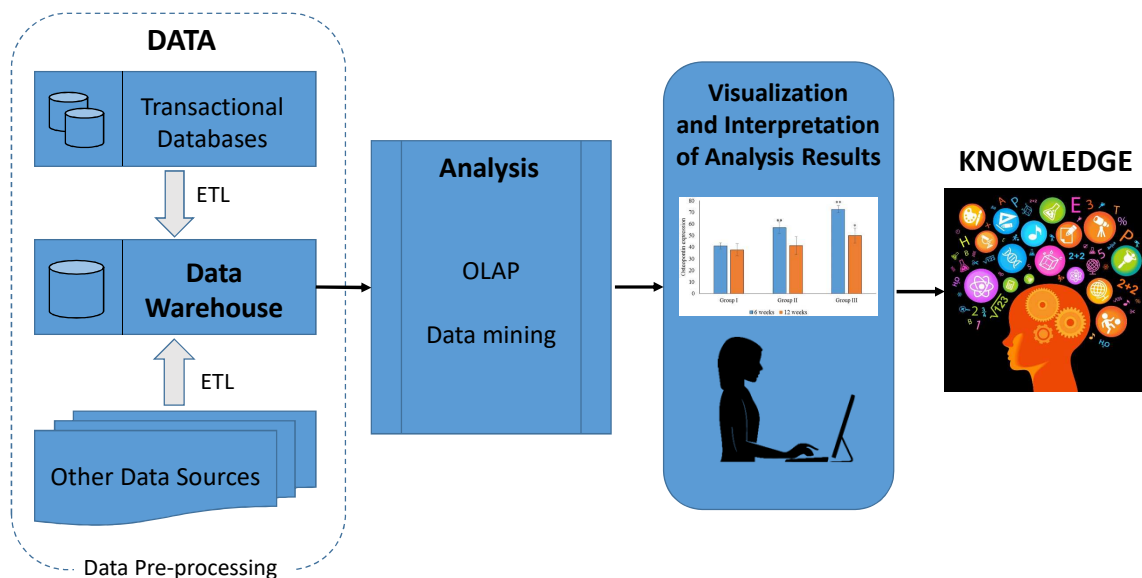

- It is of **interest** to researchers in machine learning, pattern recognition, databases, statistics, artificial intelligence, knowledge acquisition for expert systems, and data visualization.
- „Knowledge’ means here the **relationships** and **patterns** between data elements which can be extracted using a number of techniques as:

- 1) **On-Line Analytical Processing (OLAP)**
- 2) **Data mining techniques**

2024-03-18

## Knowledge Discovery from Data – A Schematic View

## Business Intelligence

- ☞ Business Intelligence (BI) is actually a content-free expression, so it possibly **means different things to different people**.
- ☞ It is an umbrella-term that **combines**: architectures, tools, methodologies and data repositories and the related groups of users
- ☞ The **major objective** is to enable interactive access to data to enable manipulation of data and to give business managers and analysts the ability to conduct appropriate analysis.
- ☞ The **process of BI** is based on the transformation of **data** to **information**, then to **decisions**, and finally to **actions**.

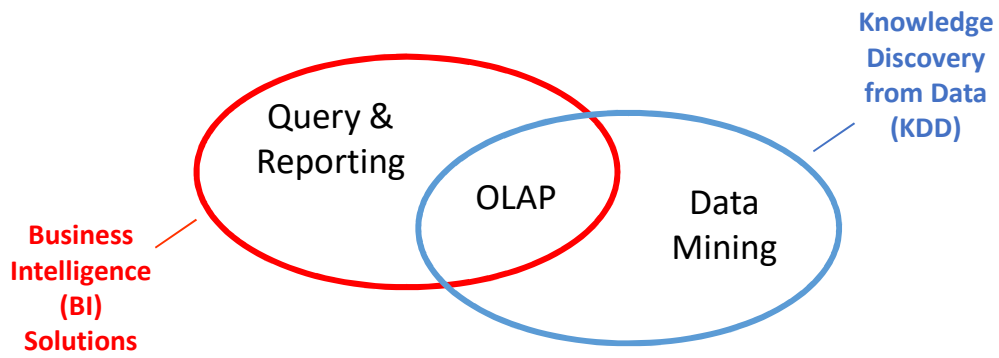

2024-03-18

## Business Intelligence and Decision Support Systems

- ☞ **Business intelligence** comprises a collection of methodologies, processes, architectures, and technologies that transform raw data into meaningful and useful information for **decision making**.
- ☞ Business intelligence and **decision-support systems** provide assistance to managers at various organizational levels for analyzing strategic information.
  - These systems collect vast amounts of data and **reduce** them to a form that can be used **to analyze organizational behavior**.
  - This data **transformation** comprises a set of tasks that take the data from the sources and, through extraction, transformation, integration, and cleansing processes, store the data in a common repository called a **data warehouse**.
- ☞ Data warehouses have been developed and deployed as an **integral part** of decision support systems to provide an infrastructure that enables users to obtain efficient and accurate responses to complex queries.
